ABSTRACT:

Background: Recently, there have been several new atypical antipsychotics introduced in Ontario; however the impact of these agents on prescribing rates and costs is unknown.

Methods: We performed a population-based cross-sectional study of adults aged 65 and over using atypical antipsychotics in Ontario from 2007 to 2013. We conducted time-series analysis to assess the impact of the introduction of new atypical antipsychotics on atypical antipsychotic utilization rates and expenditures.

Results: Rates of atypical antipsychotic use increased following the introduction of new agents in 2009, from 27.6 users per 1000 population in Q3 2009 to 29.1 users per 1000 population in Q1 2013 ($p=0.04$). Although prescribing rates for the newer atypical agents (aripiprazole, ziprasidone, and paliperidone) remained low relative to their older counterparts (olanzapine, risperidone, quetiapine), rates of aripiprazole use rose to 1.0 users per 1000 population by the end of the study period. The proportion of prescriptions that were for brand-name agents fell from 57.5% in Q2 2007 to 6.1% in Q2 2009, before rising to 11.7% by Q1 2013 following introduction of new drugs. At the end of the study period, new atypical antipsychotic agents were used by 4.3% of atypical antipsychotic users, but accounted for 14% (\$1.2M of \$8.5M) of publicly funded atypical antipsychotic expenditures.

Conclusions: Although their overall prevalence of use remains low, the introduction of new atypical antipsychotic agents has led to increased prescribing of this class of drugs in the elderly. Given the potential cost implications, further monitoring of these trends would be prudent.

BACKGROUND:

1
2
3
4
5
6
7 Antipsychotic drug therapy is a mainstay in the treatment of psychosis and related
8
9 disorders. Since the introduction of atypical antipsychotics in the 1990s, the utilization and
10
11 costs associated with these drugs has increased substantially (1-6). This was driven primarily by
12
13 prescriber preference for atypical (or second-generation) antipsychotics(1,2), higher costs of
14
15 newer agents compared with typical (or first-generation) antipsychotics(1), and a widening
16
17 range of on- and off-label uses (3-5,7-9). The increase in use of atypical antipsychotic
18
19 medications has been particularly significant in older adults with dementia (8,10-12). Since the
20
21 early 2000s, there has been a growing appreciation for antipsychotic-related adverse effects
22
23 among older persons with dementia, prompting warnings from the manufacturers and Health
24
25 Canada regarding the safety of these products (2). Although concerns around safety slowed the
26
27 growth of antipsychotic prescribing, rates of use continued to increase between 2000 and 2007
28
29 (2).
30
31
32
33
34
35

36
37 Between 2007 and 2013, several changes to antipsychotic availability and funding would
38
39 affect the costs of these drugs. Introduction of generic versions of risperidone, quetiapine and
40
41 olanzapine between 2006 and 2008 resulted in substantially lower prices for these products.
42
43 Furthermore, in 2010, the Ontario government reduced generic drug prices from 50% of the
44
45 brand-name equivalent to 25% (13). Although these events would be expected to decrease
46
47 costs associated with antipsychotic drug therapy in Ontario, soon, three new medications --
48
49 paliperidone, ziprasidone, and aripiprazole -- would receive regulatory approval and be added
50
51 to the ODB formulary (14-16). The impact of the competing forces of high relative cost and
52
53 potential for rapid uptake of newer, brand-name agents (17-20) and the greater availability and
54
55
56
57
58
59
60

1
2
3 lower prices of generic drugs is uncertain. Accordingly, we sought to investigate the impact of
4
5 the introduction of the newer brand name atypical antipsychotics (starting with paliperidone in
6
7 2009) on atypical antipsychotic prescribing rates, prevalence of brand-name antipsychotic
8
9 utilization, and related drug benefit expenditures.
10
11

12 13 **METHODS:**

14
15 We conducted a population-based serial cross-sectional time series analysis of Ontario
16
17 residents aged 65 and older who were dispensed an antipsychotic between Jan 1 2007 and
18
19 March 31 2013. These patients have universal access to physician services, hospital care, and
20
21 publicly funded drugs. This study was approved by the Research Ethics Board of the Sunnybrook
22
23 Health Sciences Centre, Toronto, Ontario.
24
25
26
27
28

29 **Data Sources**

30
31 We used large population-based administrative databases to conduct this study. These
32
33 databases were linked using unique, encoded identifiers and analyzed at the Institute for
34
35 Clinical Evaluative Sciences. The Ontario Drug Benefit (ODB) database contains records of all
36
37 prescriptions dispensed to public drug plan recipients in Ontario. This database was used to
38
39 identify the number and cost of all prescriptions for atypical antipsychotics dispensed over our
40
41 study period. The The Ontario Health Insurance Plan (OHIP) Registered Persons Database (RPDB)
42
43 contains basic demographic information (including date of birth, sex, and date of death) for all
44
45 residents of Ontario who have ever received a health card. Finally, the Contact Database
46
47 combines OHIP registration data and health care usage data to maintain a list of individuals
48
49 eligible for physician and hospital care services in Ontario. It was used to determine the size of
50
51 the population of Ontario Health Insurance Plan (OHIP)-eligible individuals over our study
52
53
54
55
56
57
58
59
60

1
2
3 period. The Contact Database was unavailable for the last quarter of the study period;
4
5 therefore we generated a quadratic least-squares regression model in order to obtain
6
7 population estimates for this final time point ($R^2 = 0.997$).
8
9

10 11 12 13 **Rates of Atypical Antipsychotic Use** 14

15
16 We examined the use of all atypical antipsychotics that were listed on the ODB formulary over
17
18 the study period, namely quetiapine, olanzapine, risperidone, paliperidone, ziprasidone, and
19
20 aripiprazole. In each calendar quarter of the study period, we identified all individuals aged 65
21
22 years or older who filled at least one prescription for an atypical antipsychotic, and reported
23
24 the number of people who used atypical antipsychotics, overall and stratified by atypical
25
26 antipsychotic agent. Rates of atypical antipsychotic use were calculated as a percentage of the
27
28 population of OHIP-eligible Ontario residents aged 65 and older and alive at the beginning of
29
30 each quarter.
31
32
33
34
35
36
37
38

39 **Prevalence of Brand-name Agents, and Antipsychotic Expenditures** 40

41 For each quarter, we determined the total quarterly cost to the provincial drug plan of atypical
42
43 antipsychotic prescriptions dispensed to patients aged 65 and older, and estimated the average
44
45 cost per prescription. This analysis was conducted overall, and stratified by each atypical
46
47 antipsychotic agent. To estimate the quarterly market share of brand-name prescriptions, we
48
49 then classified all atypical antipsychotic prescriptions according to their generic status and
50
51 found the proportion of prescriptions that were for brand-name agents.
52
53
54
55
56
57
58
59
60

Statistical Analyses

We conducted time series analysis using interventional autoregressive integrated moving-average (ARIMA) models to examine the impact of the introduction of new brand name atypical antipsychotics on overall rates of atypical antipsychotic use. Due to close temporal relation of the new agents' introduction, we chose the marketing of the first new agent as our main intervention point in the model (paliperidone, Q3 2009). We used the correlograms depicting autocorrelation, partial autocorrelation, and inverse autocorrelation functions to guide initial model selection. We assessed autocorrelation at various lags using the Ljung-Box Chi-square statistic and stationarity using the augmented Dickey-Fuller test. Our intervention was modeled as a step function in the regression model. A p-value <0.05 was considered statistically significant. All analyses were conducted using SAS software version 9.2.

RESULTS

Overall Atypical Antipsychotic Use and Choice of Agent

Over the study period, we identified 235 267 older adults who were prescribed an atypical antipsychotic in Ontario. On average, atypical antipsychotic users were aged 79 years (standard deviation 8.9), and 39.6% (N=93 200) were male. Risperidone was the most commonly used agent at the beginning of the study period (13.0 users per 1000 older adults, Q1 2007; N=23 107), followed by quetiapine (9.3 users per 1000 older adults, Q1 2007; N=16 436) and olanzapine (7.6 users per 1000 older adults, Q1 2007; N=13 570; Figure 1). Over the subsequent six years, quetiapine use rose to become the most commonly used atypical antipsychotic in the first quarter of 2013, with a prevalence of 15.1 users per 1000 older adults (N=32 532).

1
2
3 Following their introduction in Q3 2009, use of new brand name agents increased, reaching a
4 high of 1.5 users per 1000 older adults in Q1 2013 (N=3,132; Figure 1). This rise was driven
5 largely by aripiprazole use, which reached a rate of 1.0 users per 1000 older adults (N=2,120;
6 Figure 1). Overall, the introduction of brand name agents in Ontario led to a small, but
7 statistically significant increase in the overall rate of atypical antipsychotic use, from 27.6 users
8 per 1000 older adults (Q3 2009) to 29.1 users per 1000 older adults (Q1 2013; Figure 2; p=0.04).
9
10
11
12
13
14
15
16
17
18

19 **Market Share of Brand Name Agents and Atypical Antipsychotic Expenditures**

20
21 Following the introduction of generic versions of olanzapine and quetiapine between the
22 start of our study period (Q1 2007) and Q2 2009, the prevalence of brand name antipsychotic
23 agents decreased considerably from 57.5% to 6.1% (Figure 3). However, following the
24 introduction of new agents in the third quarter of 2009, the prevalence of branded agents
25 began to rise, reaching 11.7% by the end of the study period.
26
27
28
29
30
31
32
33

34 The costs for atypical antipsychotics were also greatly influenced by the introduction of
35 generic formulations early in the study period as well as the decrease in government
36 reimbursement for generic drugs in Q3 2010. Following these changes, the average cost per
37 atypical antipsychotic prescription fell from \$26.46 (Q1 2007) to a low of \$14.00 (Q4 2010;
38 Figure 3). However the costs rose 17.6% from Q4 2010 to Q1 2013, from a mean of \$14.00 per
39 prescription to a mean of \$16.39 per prescription.
40
41
42
43
44
45
46
47
48

49 In the first quarter of 2013, the newly introduced medications (aripiprazole, ziprasidone,
50 and paliperidone) were used by only 4.3% of atypical antipsychotic users (Figure 1), but
51 accounted for 16.3% of total atypical antipsychotic expenditures (\$1.4M of \$8.8M). This was
52 driven by the large differential in the average quarterly costs per person for these branded and
53
54
55
56
57
58
59
60

1
2
3 generic agents. In the first quarter of 2013, average quarterly costs per user for paliperidone,
4
5 ziprasidone and aripiprazole were \$953.76, \$362.64, and \$349.60, respectively. In comparison,
6
7 the mean quarterly costs per patient for generic atypical agents at this time were \$104.59 for
8
9 quetiapine, \$110.40 for risperidone and \$152.75 for olanzapine.
10
11
12
13
14
15

16 **DISCUSSION:**

17
18 Over the study period, we found large shifts in atypical antipsychotic prescribing
19
20 preferences and drug costs among seniors in Ontario, and an overall increase in the rate of
21
22 atypical antipsychotic prescribing following the introduction of new brand name agents to the
23
24 public drug formulary. As expected, we observed a marked decrease in expenditures
25
26 corresponding with the introduction of generic agents, and a reversal of this trend with the
27
28 arrival of novel atypical agents. Although newer branded agents were used by less than 5% of
29
30 patients treated with atypical antipsychotics in early 2013, these agents accounted for over
31
32 15% of atypical antipsychotic drug costs. Furthermore, the growth of aripiprazole use shows no
33
34 sign of slowing, and due to its high price compared to generic formulations, it is likely that costs
35
36 for atypical antipsychotic agents will continue to rise in the near future.
37
38
39
40
41
42

43
44 Several limitations of this study warrant emphasis. First, we are unable to access in-
45
46 hospital medication records, and thus our study is restricted to atypical antipsychotic use in
47
48 community-dwelling seniors and long-term care residents. Second, due to the close proximity
49
50 of the introduction of new antipsychotic agents and generic versions of existing agents, we
51
52 were unable to assess the independent impact of each new antipsychotic agent on drug
53
54 expenditures using time series analysis.

35
36
37
38
39
40
Previous studies have found expanding off-label prescribing and potential overuse of atypical antipsychotics, suggesting that the rising rate of use of these products after the introduction of new agents should be further monitored and explored to assess the appropriateness of these prescribing practices (1,2,7,8). Furthermore, the safety of antipsychotic use in older patients has been questioned, particularly for the symptomatic treatment of behavioural and psychological symptoms of dementia (2,12). Adverse effects observed include extrapyramidal symptoms and increased risk of diabetes, hip fracture, and all-cause mortality (6,21-23). Notably, Health Canada and Janssen Inc. have recently agreed to limit risperidone use in dementia to short-term symptomatic treatment of behavioural or psychological symptoms of severe Alzheimer type dementia, citing a higher risk of cerebrovascular adverse events (24). However, previous studies have found safety warnings to be ineffective at reducing the use of antipsychotics among the older population in Canada and Europe, and our findings indicate that, while prescribing preferences have shifted within the class as product availability has changed, atypical antipsychotics are increasingly a mainstay of geriatric psychiatry, despite these safety concerns (2,12).

41 **CONCLUSION:**

42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60
The results of this study suggest that the introduction of new atypical antipsychotic agents, which are more aggressively marketed than generic therapies (25-27), led to a small but significant increase in the overall use of these medications in Ontario. Furthermore, we demonstrated that, despite a drop in atypical antipsychotic costs following the introduction of several generic formulations, expenditures related to these drugs are once again rising. Further monitoring of these trends and their impact on patient outcomes and health sector

1
2
3 expenditures would be prudent as they have the potential to have considerable impacts on
4
5
6 quality of care and drug formulary budgets.

Figure 3: Cost per antipsychotic prescription and prevalence of branded atypical antipsychotic agents.

Legend

- a. Olanzapine patent expiry
- b. Quetiapine patent expiry
- c. Paliperidone added to formulary
- d. Olanzapine rapid dissolve patent expiry
- e. Quetiapine extended release added to formulary
- f. Ziprasidone added to formulary
- g. Aripiprazole added to formulary
- h. Injectable paliperidone added to formulary
